

# Secondary Analysis of Photochemical Modeling Data Report

---

*Prepared by the Capital Area Council of Governments  
June 15, 2018*

PREPARED UNDER A GRANT FROM THE TEXAS COMMISSION ON ENVIRONMENTAL QUALITY

The preparation of this report was financed through grants from the State of Texas through the Texas Commission on Environmental Quality. The content, findings, opinions, and conclusions are the work of the author(s) and do not necessarily represent findings, opinions, or conclusions of the TCEQ.

## **Executive Summary**

---

This report provides insights into ground-level ozone (O<sub>3</sub>) formation in the Austin-Round Rock Metropolitan Statistical Area (MSA) using existing photochemical modeling completed by the Capital Area Council of Governments (CAPCOG), the Alamo Area Council of Governments (AACOG), the Texas Commission on Environmental Quality (TCEQ), and the U.S. Environmental Protection Agency (EPA).

Analyses developed for this report include the following:

- Projected Maximum Daily 8-Hour O<sub>3</sub> Average (MDA8 O<sub>3</sub>) within the region and estimated probabilities of violating the 2015 O<sub>3</sub> National Ambient Air Quality Standard (NAAQS) of 70 parts per billion (ppb) from 2018 – 2023 (Section 2)
- Analysis of factors influencing the impact of O<sub>3</sub> precursor emissions on ground-level O<sub>3</sub> formation in the Austin-Round Rock MSA (Section 3)
- Estimated impacts of emission reduction strategies within the MSA (Section 5)
- Implications of other recent regional development on O<sub>3</sub> formation within the MSA (Section 6)

## Table of Contents

Executive Summary.....	2
Table of Contents.....	3
1 Introduction .....	5
2 Projected Ozone Levels and Risks of Violating the NAAQS through 2023.....	5
2.1 AACOG 2017, 2020, and 2023 Modeling .....	5
2.2 Projected 4 <sup>th</sup> -High MDA8 O <sub>3</sub> Levels and Design Values .....	7
2.3 Probabilities of Design Values Exceeding the O <sub>3</sub> NAAQS by Year .....	9
3 Analysis of Factors Influencing Impact of Precursor Emissions within the MSA on O <sub>3</sub> Formation ....	12
3.1 Type of Emissions: NO <sub>x</sub> or VOC.....	12
3.2 Location of Emissions: O <sub>3</sub> to NO <sub>x</sub> Ratios for Austin-Round Rock MSA Counties .....	12
3.3 Timing of Emissions: Hour of Day .....	14
4 Estimated Impact of Emission Reduction Strategies Through 2023 .....	15
4.1 Across-the-Board Reductions in NO <sub>x</sub> and VOC Emissions .....	15
4.2 Inspection & Maintenance Program.....	16
4.3 TERP Grants.....	18
4.4 Reducing NO <sub>x</sub> Emissions at Decker Creek Power Plant .....	19
4.5 Comparison of Impact Ratios.....	21
5 Implications of Other Recent Regional Developments on Ozone .....	22
5.1 Gasoline Sulfur Reductions .....	22
5.2 Shut-Down of Three Coal-Fired Power Plants in 2018.....	26
6 Conclusions .....	27
Appendix .....	29
Table 2-1. CAMS 3 Modeled MDA8 O <sub>3</sub> Levels for 2017, 2020, and 2023 for Selected Days .....	6
Table 2-2. CAMS 38 Modeled MDA8 O <sub>3</sub> Levels for 2017, 2020, and 2023 for Selected Days .....	7
Table 2-3. Change in Probabilities of Austin-Round Rock MSA Attaining a 65 ppb, 70 ppb, and 75 ppb NAAQS in 2021 from a 0.5 ppb, 0.7 ppb, and 1.0 ppb change in Design Value.....	11
Table 4-1. CAMS 3 Sensitivity to Across-the-Board NO <sub>x</sub> and VOC Reductions from June 2006 Model .....	15
Table 4-2. CAMS 3 Sensitivity to Across-the-Board NO <sub>x</sub> and VOC Reductions from June 2006 Model .....	16
Table 4-3. Modeled Impact of I/M Program on Top 10 2012 MDA8 O <sub>3</sub> Levels at CAMS 3 and 38 (reference: baseline).....	16
Table 4-4. MDA8 O <sub>3</sub> Impact - NO <sub>x</sub> Emissions Change Impact Ratios for On-Road TERP Grants, 2012.....	18
Table 4-5. MDA8 O <sub>3</sub> Impact - NO <sub>x</sub> Emissions Change Impact Ratios for Non-Road TERP Grants, 2012.....	19
Table 4-6. MDA8 O <sub>3</sub> Impact - NO <sub>x</sub> Emissions Change Impact Ratios from Decker Unit 1 NO <sub>x</sub> , June 2012.	20
Table 4-7. MDA8 O <sub>3</sub> Impact - NO <sub>x</sub> Emissions Change Impact Ratios from Decker Unit 2 NO <sub>x</sub> , June 2012.	21
Table 4-8. MDA8 O <sub>3</sub> Impact - NO <sub>x</sub> Emissions Change Impact Ratios from Decker Turbine NO <sub>x</sub> , June 2012 .....	21
Table 4-9. Decker Creek Power Plant 2017 Ozone Season Day (OSD) NO <sub>x</sub> Emissions (tpd).....	21
Table 5-1. Emissions Inputs for Final Tier 3 Vehicle Standards.....	23
Table 5-2. 2017 Gasoline Sulfur Content Sampled in the Austin District (ppm).....	24

Table 5-3. NO<sub>x</sub> Emissions for Tier 2 and Older Gasoline Vehicles from TTI MOVES 2010 Sensitivity Analysis, 2016-2023 ..... 25

Figure 5-3. Comparison of NO<sub>x</sub> Emissions for Gasoline Vehicles Relative to 2016 based on 10 ppm and 30 ppm Gasoline Sulfur Scenarios ..... 26

## 1 Introduction

---

The purpose of this project is to gain additional insights into ground-level ozone formation within the region based on photochemical modeling that has already been conducted. In some cases, this will involve focusing what the implications are for the CAPCOG region of data developed by other agencies, while in other cases, CAPCOG will use photochemical modeling data that was developed for the CAPCOG region, but will perform additional analyses beyond what was originally conducted.

This report uses existing photochemical modeling data produced by the EPA, TCEQ, CAPCOG, and AACOG in order to support CAPCOG's ongoing regional air quality planning efforts. On May 9, 2018, the Central Texas Clean Air Coalition approved moving forward with a five-year voluntary regional air quality plan covering 2019-2023 with the primary goal of maximizing the probability of the Austin-Round Rock MSA's compliance with the NAAQS and a secondary goal of otherwise minimizing health and environmental impacts of regional air pollution. In order to support this planning effort, this report looks at:

- Projected O<sub>3</sub> levels within the region between 2019 and 2023
- The probability that the region's O<sub>3</sub> design value will exceed the 2015 O<sub>3</sub> NAAQS or a potentially tighter 65 ppb O<sub>3</sub> NAAQS if EPA tightened the NAAQS in 2020
- Adjusted estimates of source contributions to the region's 2017 O<sub>3</sub> levels value based on the MSA's final 2017 design value and estimated changes in contributions through 2023
- The estimated impact of various O<sub>3</sub> control strategies that could be implemented between 2019 and 2023

## 2 Projected Ozone Levels and Risks of Violating the NAAQS through 2023

---

One of the key pieces of information needed for CAPCOG's air quality planning process is understanding the potential risks of violating the O<sub>3</sub> NAAQS during the time period covered by the plan. This section includes an analysis of these risks based on recent modeling conducted by AACOG of O<sub>3</sub> levels in 2017, 2020, and 2023, O<sub>3</sub> monitoring data at C3 and C38 in Travis County in 2015-2017, and EPA's guidance for modeling future attainment of the NAAQS.

### 2.1 AACOG 2017, 2020, and 2023 Modeling

---

CAPCOG used photochemical modeling conducted by AACOG in 2017 and 2018 and the MSA's final 2015-2017 O<sub>3</sub> monitoring data in order to project the region's O<sub>3</sub> design values and the probabilities of violating the current 2015 O<sub>3</sub> NAAQS of 70 ppb and a potentially tighter 2020 O<sub>3</sub> NAAQS of 65 ppb.

In order to project O<sub>3</sub> levels, CAPCOG used a modified version of the "modeled attainment test" as described in EPA's 2014 Draft *Modeling Guidance for Demonstrating Attainment of Air Quality Goals for Ozone, PM<sub>2.5</sub>, and Regional Haze*.<sup>1</sup>

---

<sup>1</sup> EPA. *Draft Modeling Guidance for Demonstrating Attainment of Air Quality Goals for Ozone, PM<sub>2.5</sub>, and Regional Haze*. December 2014. Available online at: [https://www3.epa.gov/ttn/scram/guidance/guide/Draft\\_O3-PM-RH\\_Modeling\\_Guidance-2014.pdf](https://www3.epa.gov/ttn/scram/guidance/guide/Draft_O3-PM-RH_Modeling_Guidance-2014.pdf)

EPA’s 2014 Draft *Modeling Guidance for Conducting Modeled Attainment Tests* recommends that, “ozone RRFs be calculated on the 10 highest days in the base year modeling at the monitor location, as long as the base MDA8 values are greater than or equal to 60 ppb for that day. In cases for which the base model simulation does not have 10 days with MDA8 O<sub>3</sub> values greater than or equal to 60 ppb at a site, then EPA recommends using all days where MDA8  $\geq$ 60 ppb, as long as there are at least 5 days that meet that criteria. If there are less than 5 days with MDA8  $\geq$ 60 ppb, EPA recommends that air agencies do not calculate a DVF [future design value] for that site.” For future values, a modeled MDA8 O<sub>3</sub> of less than 60 ppb can be used as long as the base modeling day has a modeled MDA8 O<sub>3</sub> of at least 60 ppb.

EPA’s guidance goes on: “Once the MDA8 values are selected for each appropriate day for each monitoring site, they should be averaged together over the days while maintaining at least two places to the right of the decimal (round to the last decimal digit). The RRF is the ratio of the average future MDA8 values to the average base MDA8 values.”

CAPCOG’s modified version of the attainment test involves the following two modifications of the method described in EPA’s guidance:

1. CAPCOG used the MDA8 O<sub>3</sub> values for the grid cell containing the monitor, rather than the grid cell with the highest MDA8 O<sub>3</sub> value in the base year in a 3 x 3 cell array around the cell containing the monitoring station
2. CAPCOG interpolated modeled MDA8 O<sub>3</sub> values for 2018, 2019, 2021, and 2022 based on the values modeled for 2017, 2020, and 2023
3. CAPCOG used the 4<sup>th</sup>-highest MDA8 O<sub>3</sub> value modeled in each year as an alternative basis for the RRF calculations

For CAMS 3 and 38, the following tables show:

- the modeled MDA8 O<sub>3</sub> values for each day included in the analysis
- the count of days in each year with O<sub>3</sub> levels of at least 60 ppb
- the 4<sup>th</sup>-highest MDA8 O<sub>3</sub> for each year
- the average of the MDA8 values for the top 10 days in the baseline when MDA8 O<sub>3</sub>  $\geq$ 60 ppb
- the RRF, calculated two different ways

## 2.2 Projected 4<sup>th</sup>-High MDA8 O<sub>3</sub> Levels and Design Values

CAPCOG projected 2018-2023 O<sub>3</sub> levels in terms of high, low, and average projected 4<sup>th</sup>-highest MDA8 O<sub>3</sub> concentration for each year by multiplying the RRFs for each year to the 2015, 2016, and 2017 4<sup>th</sup>-

highest MDA8 O<sub>3</sub> levels and the 2015-2017 averages of the 4<sup>th</sup>-highest MDA8 O<sub>3</sub> levels. The following figure shows the MDA8 O<sub>3</sub> levels for each of the base years and the three-year average.

**Figure 2-1. 4th-Highest MDA8 O<sub>3</sub> Monitored at C3 and C38, 2015-2017**

CAPCOG then applied the relative response factors to each of these statistics in order to generate the projected design value and simulated 4<sup>th</sup>-highest MDA8 O<sub>3</sub> values for the three years that would be used in the design value calculation for each year.

**Figure 2-2. Projected 4th-High MDA8 O<sub>3</sub> for CAMS 3, 2018-2023**

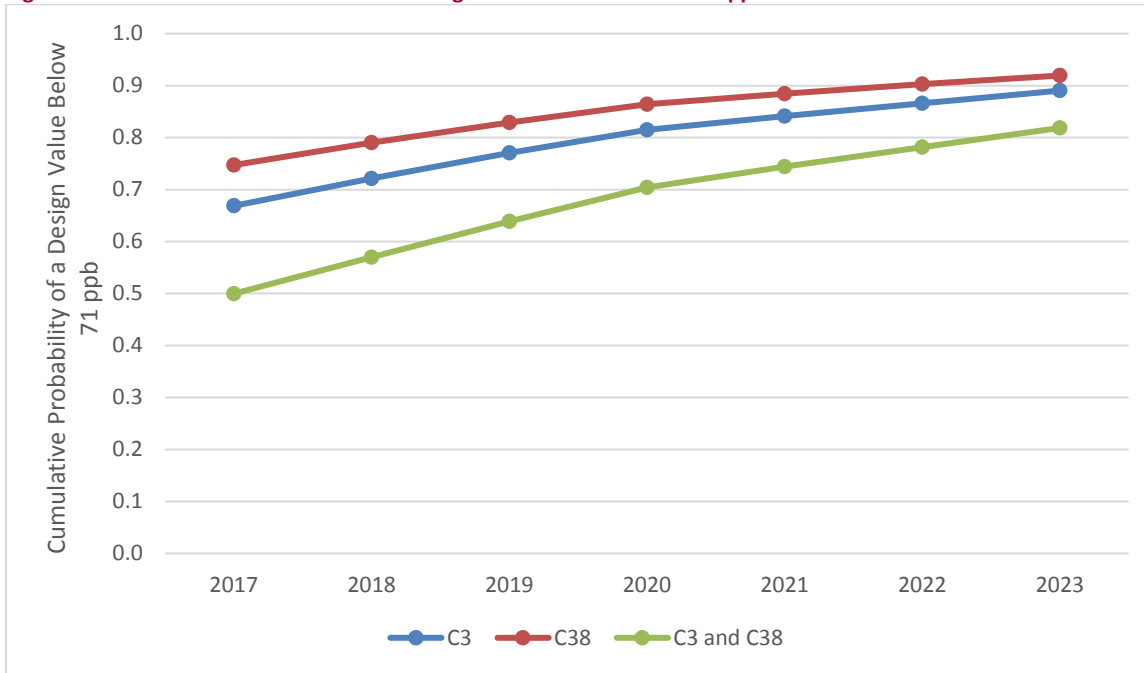

**Figure 2-3. Projected 4th-High MDA8 O<sub>3</sub> for CAMS 38, 2018-2023**

### 2.3 Probabilities of Design Values Exceeding the O<sub>3</sub> NAAQS by Year

Using the design value projection and the standard deviation among the projected values from the three bases, CAPCOG calculated the cumulative probabilities that each monitor’s design value would be below 71 ppb for each analysis year, and also the joint probability that both monitors would have a design value below 71 ppb. This is shown in the figure below.

**Figure 2-4. Probabilities that C3 and C38 Design Values Will Be Below 71 ppb**

Interestingly, the probability that both monitors would have had a design value of less than 71 ppb in 2017 was just below 50%. If EPA completes its next review of the O<sub>3</sub> NAAQS by October 1, 2020, and revises the NAAQS, it would need to complete area designations by October 1, 2022.<sup>2</sup> The following figure shows the probability of the C3, C38, and both monitors attaining a standard set at a level anywhere between 65-75 ppb at the end of the 2021 O<sub>3</sub> season.

<sup>2</sup> Section 107(d)(1)(A) of the Clean Air Act states that, “By such date as the Administrator may reasonably require, but not later than 1 year after promulgation of a new or revised national ambient air quality standard for any pollutant under section 7409 of this title, the Governor of each state shall (and at any other time the Governor of a state deems the appropriate the Governor may) submit to the Administrator a list of all areas in the state, designating as...”. Based on this language, if EPA retained an existing NAAQS at the end of a review, it may not necessarily mean that it would conduct a new round of designations.

**Figure 2-5. Probabilities of C3 and C38 2021 Design Values Complying with O<sub>3</sub> NAAQS at 65 ppb, 70 ppb, and 75 ppb Levels**

Lastly, CAPCOG calculated the change in probability of the area’s design value complying with a 65 ppb, 70 ppb, and 75 ppb NAAQS as a result of a change in the design value of 0.5 ppb, 0.7 ppb, and 1.0 ppb.

**Table 2-3. Change in Probabilities of Austin-Round Rock MSA Attaining a 65 ppb, 70 ppb, and 75 ppb NAAQS in 2021 from a 0.5 ppb, 0.7 ppb, and 1.0 ppb change in Design Value**

Change in Design Value	75 ppb NAAQS	70 ppb NAAQS	65 ppb NAAQS
Minus 1.0 ppb	0.013	0.072	0.092
Minus 0.7 ppb	0.010	0.052	0.063
Minus 0.5 ppb	0.007	0.038	0.045
Plus 0.5 ppb	-0.009	-0.041	-0.041
Plus 0.7 ppb	-0.014	-0.059	-0.057
Plus 1.0 ppb	-0.021	-0.086	-0.079

This analysis shows that:

- A 0.5 ppb change in the area’s 2021 design value would be expected to have a 0.007 – 0.045 impact on the probability of attaining an O<sub>3</sub> NAAQS set at these levels
- A 0.7 ppb change in the area’s 2021 design value would be expected to have a 0.010 – 0.063 impact on the probability of attaining an O<sub>3</sub> NAAQS set at these levels
- A 1.0 ppb change in the area’s 2021 design value would be expected to have a 0.013 – 0.092 impact on the probability of attaining an O<sub>3</sub> NAAQS set at these levels

### 3 Analysis of Factors Influencing Impact of Precursor Emissions within the MSA on O<sub>3</sub> Formation

---

This section provides analysis of three factors relevant to the impact of O<sub>3</sub> precursor emissions (NO<sub>x</sub> and VOC) on MDA8 O<sub>3</sub> formation within the region. This includes:

- Type of emissions (NO<sub>x</sub> or VOC)
- Location of emissions (by county)
- Timing of emissions (by hour of day)

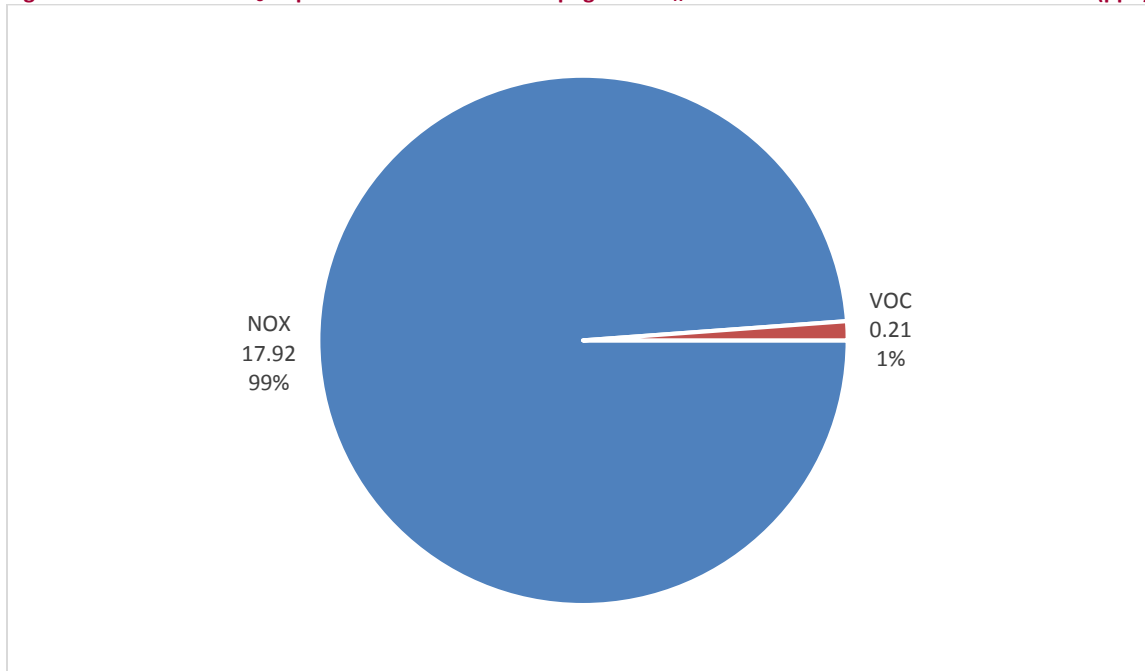

These analyses can be used to design or enhance the effectiveness of pollution control strategies.

#### 3.1 Type of Emissions: NO<sub>x</sub> or VOC

---

AACOG's 2017 source apportionment modeling for CAPCOG provided the impact of anthropogenic emissions from within the Austin-Round Rock MSA by precursor type. The following chart indicates the impact of anthropogenic NO<sub>x</sub> emissions v. anthropogenic VOC emissions from within the MSA.<sup>3</sup>

**Figure 3-1. 2017 MDA8 O<sub>3</sub> Impacts at CAMS 3 of Anthropogenic NO<sub>x</sub> and VOC Emissions from within the MSA (ppb)**

#### 3.2 Location of Emissions: O<sub>3</sub> to NO<sub>x</sub> Ratios for Austin-Round Rock MSA Counties

---

One of the questions posed in the QAPP for this project was: "What additional data can be developed from analyzing the source apportionment modeling data provided by AACOG under Task 6.1 of CAPCOG's Fiscal Year (FY) 2016-2017 work plan that may not have been within scope of the final report provided by CAPCOG to the TCEQ but are still useful for the CAPCOG region's air quality planning efforts?"

---

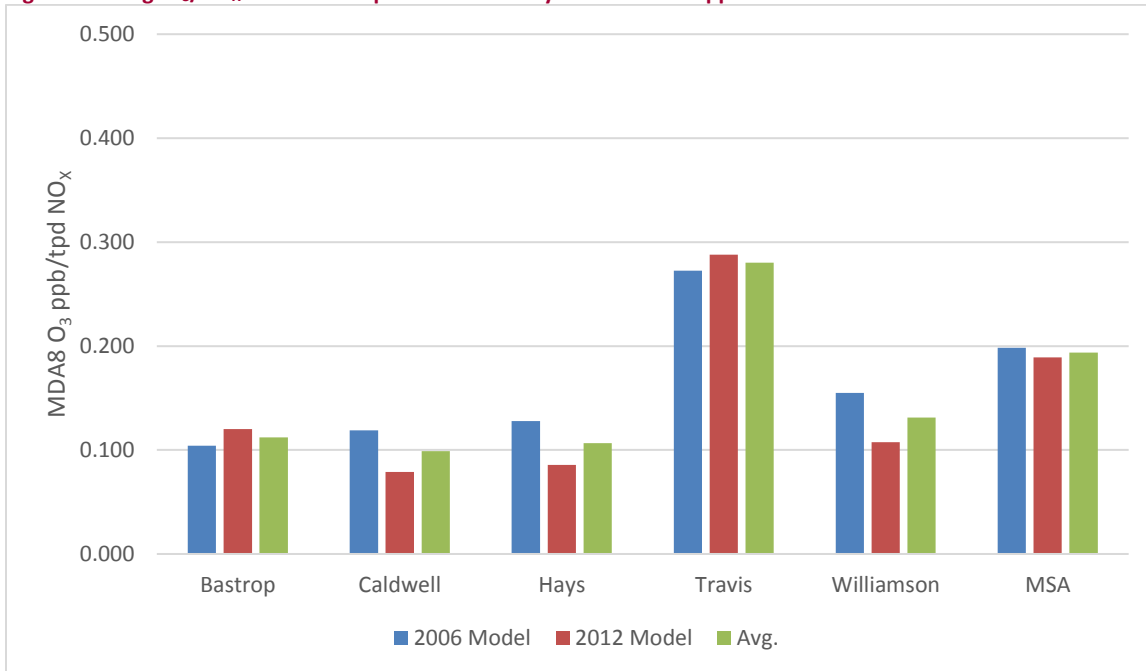

<sup>3</sup> [http://www.capcog.org/documents/airquality/reports/2017/6.1.2-CAPCOG\\_Source\\_Apportionment\\_Modeling\\_Report.pdf](http://www.capcog.org/documents/airquality/reports/2017/6.1.2-CAPCOG_Source_Apportionment_Modeling_Report.pdf)

CAPCOG obtained from AACOG the NO<sub>x</sub> emissions for Bastrop, Caldwell, Hays, Travis, and Williamson Counties used for the 2017 source apportionment modeling project in order to calculate the average contribution of each county's emissions to CAMS 3 and CAMS 38 MDA8 O<sub>3</sub> levels per ton of emissions. These ratios are shown in the figure below.

**Figure 3-2. Avg. O<sub>3</sub>/NO<sub>x</sub> Ratios for Top 10 Modeled Days for 2017 ≥ 60 ppb at CAMS 3**

**Figure 3-3. Avg. O<sub>3</sub>/NO<sub>x</sub> Ratios for Top 10 Modeled Days for 2017 ≥ 60 ppb at CAMS 38**

These data suggest that the CAMS 3 O<sub>3</sub> design value is 3.1 – 3.3 times more sensitive to NO<sub>x</sub> emissions from Travis County than NO<sub>x</sub> emissions from the rest of the MSA, and that the CAMS 38 O<sub>3</sub> design value is 2.1 – 2.9 more sensitive to NO<sub>x</sub> emissions from Travis County than the rest of the MSA. For both stations, NO<sub>x</sub> emissions from Travis County have about 1.4 – 1.6 times the impact as NO<sub>x</sub> emissions from the MSA as a whole.

One of the implications of these data is that control strategy analyses that use the cost per ton of NO<sub>x</sub> reduced as a point of comparison would benefit from accounting for additional O<sub>3</sub> reduction benefits of NO<sub>x</sub> reductions in certain counties compared to others. A cost per ppb of O<sub>3</sub> reduction would be a better point of comparison for these types of projects. For example, one of the projects funded in the Austin area from the last round of Texas Emission Reduction Plan (TERP) Emission Reduction Incentive Grant (ERIG) projects provided \$122,500.00 for the replacement of a truck in order to achieve 14.3547 tons of NO<sub>x</sub> emissions over 7 years. This project would achieve a cost efficiency ratio of \$8,532 per ton of NO<sub>x</sub> reduced, and \$21,800,341 per ton per day (tpd) of NO<sub>x</sub> reductions over the seven-year period. If these emissions reductions were to occur across the MSA, the project would result in a cost efficiency ratio of \$113 million per ppb of O<sub>3</sub> reduction at CAMS 38, for instance, but would result in a ratio of \$77 million per ppb of O<sub>3</sub> reduction at CMS 38 if the emissions reductions were concentrated in Travis County.

### **3.3 Timing of Emissions: Hour of Day**

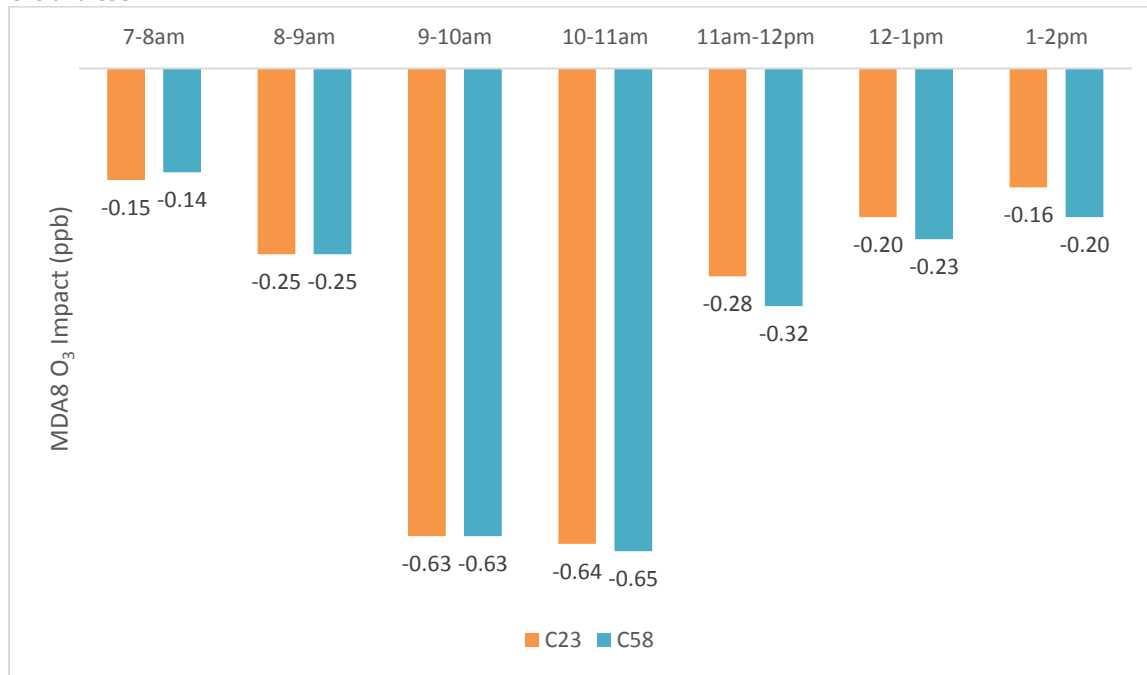

---

One of the other key factors influencing the impact of emissions on MDA8 O<sub>3</sub> levels is the timing of emissions, and in particular, the hour of the day in which emissions are occurring. In 2015, AACOG completed photochemical modeling that involved reductions in one on of on-road NO<sub>x</sub> emissions for each hour from 7 am – 2 pm across the San Antonio-New Braunfels MDA on MDA8 O<sub>3</sub> levels at its two “downwind” regulatory O<sub>3</sub> monitors. The following graph illustrates the impact.<sup>4</sup>

---

<sup>4</sup> <http://aacog.com/DocumentCenter/View/34698/Ozone-Analysis-June-2006-Photochemical-Modeling-Episode-Dated-10-2015-PDF-Version---MPO>

**Figure 3-4. Impact of 1 ton of On-Road NO<sub>x</sub> Emission Reductions from San Antonio-New Braunfels MSA on MDA O<sub>3</sub> levels at C23 and C58**

While the numbers for the Austin-Round Rock MSA would be expected to be somewhat different, the general pattern would be expected to be seen in the relationship between NO<sub>x</sub> emissions and O<sub>3</sub> levels in the Austin-Round Rock MSA as well.

## 4 Estimated Impact of Emission Reduction Strategies Through 2023

One of the key pieces of information for CAPCOG’s planning efforts is understanding the impact of various emission reduction strategies within the region. This section provides a synthesis of data produced from several different modeling studies carried out by CAPCOG from 2013 to 2017.

### 4.1 Across-the-Board Reductions in NO<sub>x</sub> and VOC Emissions

In 2012, the University of Texas at Austin (UT) conducted sensitivity modeling for CAPCOG that involved across-the-board reductions in NO<sub>x</sub> and VOC emissions from the Austin-Round Rock MSA and modeling the O<sub>3</sub> impact at CAMS 3, CAMS 38, and Travis County as a whole.<sup>5</sup> The following tables summarizes the calculated ratios of CAMS 3 and 38 MDA8 O<sub>3</sub> reductions to reductions in NO<sub>x</sub> and VOC from this study for all days with baseline MDA8 O<sub>3</sub> ≥ 60 ppb.

**Table 4-1. CAMS 3 Sensitivity to Across-the-Board NO<sub>x</sub> and VOC Reductions from June 2006 Model**

Scenario	NO <sub>x</sub> Ratio (O <sub>3</sub> ppb/tpd NO <sub>x</sub> )	VOC Ratio (O <sub>3</sub> ppb/tpd NO <sub>x</sub> )	NOX/VOC Ratio
<b>25% Reduction from Baseline</b>	0.0615	0.0018	34.2897
<b>50% Reduction from Baseline</b>	0.0700	0.0019	37.7893

<sup>5</sup> [http://www.capcog.org/documents/airquality/reports/2013/Task\\_8.3-Precursor\\_Response\\_Runs\\_Final.pdf](http://www.capcog.org/documents/airquality/reports/2013/Task_8.3-Precursor_Response_Runs_Final.pdf)

Scenario	NO <sub>x</sub> Ratio (O <sub>3</sub> ppb/tpd NO <sub>x</sub> )	VOC Ratio (O <sub>3</sub> ppb/tpd NO <sub>x</sub> )	NOX/VOC Ratio
Reduction to 50% from 25%	0.0786	0.0019	41.0717

**Table 4-2. CAMS 3 Sensitivity to Across-the-Board NO<sub>x</sub> and VOC Reductions from June 2006 Model**

Scenario	NO <sub>x</sub> Ratio (O <sub>3</sub> ppb/tpd NO <sub>x</sub> )	VOC Ratio (O <sub>3</sub> ppb/tpd NO <sub>x</sub> )	NOX/VOC Ratio
25% Reduction from Baseline	0.0631	0.0018	58.3332
50% Reduction from Baseline	0.0664	0.0019	58.4878
Reduction to 50% from 25%	0.0696	0.0019	58.6287

## 4.2 Inspection & Maintenance Program

In 2015, CAPCOG partnered with AACOG to model the impact of the Travis and Williamson County vehicle emissions inspection and maintenance program on 2012 O<sub>3</sub> levels using TCEQ’s June 2006 base case photochemical modeling platform.<sup>6</sup> The following table shows the impact of the I/M program on the top 10 days in the 2012 baseline (which already included the I/M emission reductions at CAMS 3 and 38).

**Table 4-3. Modeled Impact of I/M Program on Top 10 2012 MDA8 O<sub>3</sub> Levels at CAMS 3 and 38 (reference: baseline)**

MDA8 O <sub>3</sub> Day Rank	CAMS 3 Date	CAMS 3 MDA8 O <sub>3</sub> Impact	CAMS 38 Date	CAMS 38 MDA8 O <sub>3</sub> Impact
1	6/13	0.2455	6/29	0.2294
2	6/3	0.3189	6/30	0.1453
3	6/8	0.1848	6/9	0.1552
4	6/29	0.0944	6/8	0.1449
5	6/30	0.0438	6/4	0.0983
6	6/9	0.0622	6/12	0.1292
7	6/4	0.1169	6/28	0.2093
8	6/7	0.2538	6/13	0.0421
9	6/28	0.1432	6/10	0.1024
10	6/12	0.0523	6/3	0.0910
<b>Top 10 MDA8 O<sub>3</sub> ≥ 60 ppb</b>	<b>n/a</b>	<b>0.1626</b>	<b>n/a</b>	<b>0.1517</b>

Note: for CAMS 3, the 6/12 and 6/28 dates that are in the top 10 did not have MDA8 ≥ 60 ppb and are therefore not included in the average at the bottom of the table. Similarly, 6/3, 6/10, 6/13, and 6/28 were among the top 10 days in the CAMS 38 base case scenario but had MDA8 O<sub>3</sub> below 60 ppb, and were therefore excluded from the average at the bottom of the table.

In 2015, ERG conducted a study of the emission reduction benefits of the I/M program in Travis and Williamson Counties, which included estimates of the NO<sub>x</sub> reduction benefits estimated for 2018. This study modeled a 11.47% reduction in NO<sub>x</sub> in 2018 for light-duty gasoline vehicles. CAPCOG used this

<sup>6</sup> [http://www.capcog.org/documents/airquality/reports/2015/Photochemical\\_Modeling\\_Analysis\\_Report\\_2015-09-04\\_Final\\_Combined.pdf](http://www.capcog.org/documents/airquality/reports/2015/Photochemical_Modeling_Analysis_Report_2015-09-04_Final_Combined.pdf)

assumption and calculated the NO<sub>x</sub> emissions from light-duty vehicles in Travis and Williamson Counties with and without the I/M program from 2016-2023, shown in the figure below.

**Figure 4-1. Projected Light-Duty Gasoline Vehicles NO<sub>x</sub> Emissions in Travis County with and Without the I/M Program**

The overall NO<sub>x</sub> reduction benefit shrinks over this period from 2.41 tpd in 2016 to 1.02 tpd in 2023 due to the reduction in emissions attributable to fleet turnover. CAPCOG then calculated the impact of the I/M program on CAMS 3 and 38 for 2016-2023, as shown in the figure below.

**Figure 4-2. Modeled O<sub>3</sub> Design Value Impact of I/M Program, 2016 - 2023**

CAPCOG cautions that the smaller benefits calculated further out are based on a number of assumptions about the impact of an I/M program (i.e., modeling the benefit of an I/M program based on “reference rates” from data collected on Tier 1 and older vehicles, which may not be an accurate representation of the extent of the relative benefit of an I/M program once standards are much tighter, as they are under the Tier 2 and 3 regimes. For example, if a Tier 1 vehicle certified at 0.4 grams of NO<sub>x</sub> per mile had problems with its exhaust system causing it to have a 1.0 gram per mile exhaust rate consistent with the standard for a Tier 0 light-duty vehicle, that increase of 0.6 grams per mile would represent a 15% increase in NO<sub>x</sub> emissions for a pool of 10 vehicles all certified to the Tier 1 level. However, if a Tier 2 vehicle certified at a rate of 0.07 grams per mile and was having problems with its exhaust system causing it to have a 1.0 gram per mile exhaust rate, that would represent a 0.93 gram per mile increase, that would mean that a group of 10 Tier 2 vehicles that included that one vehicle would now have an average emissions rate of 0.163 grams per mile, 113% higher than the Tier 2 level. The failure of a pollution control system in a Tier 2-certified or Tier-3 certified vehicle could have a much larger relative impact on the area’s NO<sub>x</sub> emissions than the above analysis would represent.

### 4.3 TERP Grants

In 2017, CAPCOG and AACOG partnered to model the impact of NO<sub>x</sub> emission reductions from TERP grants awarded to the Austin-Round Rock MSA on 2012 MDA8 O<sub>3</sub> levels using TCEQ’s June 2012 base case modeling platform.<sup>7</sup> CAPCOG and AACOG modeled the on-road and non –road TERP grant emission reductions separately. Since the 2012 emissions inventory inputs for on-road sources already accounted for the emission reductions from the TERP grants due to the impact on the age distribution input for the MOTO Vehicle Emissions Simulator (MOVES) model, CAPCOG and AACOG modeled what the O<sub>3</sub> levels across the 4 k m x 4 km grid would be if on-road emissions within the Austin-Round Rock MSA in 2012 had not already been reduced through these grants.

The following table shows the MDA8 O<sub>3</sub>/NO<sub>x</sub> emissions impact ratios for the top 10 days modeled for the baseline at CAMS 3 and 38 (each monitor had more than 10 days with MDA8 O<sub>3</sub> ≥ 60 ppb during this period).

**Table 4-4. MDA8 O<sub>3</sub> Impact - NO<sub>x</sub> Emissions Change Impact Ratios for On-Road TERP Grants, 2012**

Baseline MDA8 O <sub>3</sub> Rank	CAMS 3 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )	CAMS 38 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )
1	0.1452	0.1266
2	0.0718	0.1302
3	0.0421	0.1021
4	0.0707	0.1969
5	0.0596	0.0911
6	0.1384	0.0702
7	0.0523	0.0413
8	0.0346	0.0827

<sup>7</sup> [http://www.capcog.org/documents/airquality/reports/2017/6.3.2a-AACOG\\_Sensitivity\\_and\\_Control\\_Strategy\\_Modeling\\_Report.pdf](http://www.capcog.org/documents/airquality/reports/2017/6.3.2a-AACOG_Sensitivity_and_Control_Strategy_Modeling_Report.pdf)

Baseline MDA8 O <sub>3</sub> Rank	CAMS 3 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )	CAMS 38 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )
9	0.0452	0.0655
10	0.0378	0.0483
<b>Avg. Top 4 Days</b>	0.0858	0.1339
<b>Avg. Top 10 Days</b>	0.0676	0.0899

For non-road sources, since the age distribution is an intermediate model output in the Texas NONROAD (TexN) model, the TERP emission reductions are not already accounted for in the existing modeling inventories. Therefore, CAPCOG modeled a reduction in NO<sub>x</sub> emissions from non-road sources consistent with the emission reductions actually achieved through 2012 from non-road sources in the Austin area. The following table shows the NO<sub>x</sub> impact ratios for non-road TERP emission reductions.

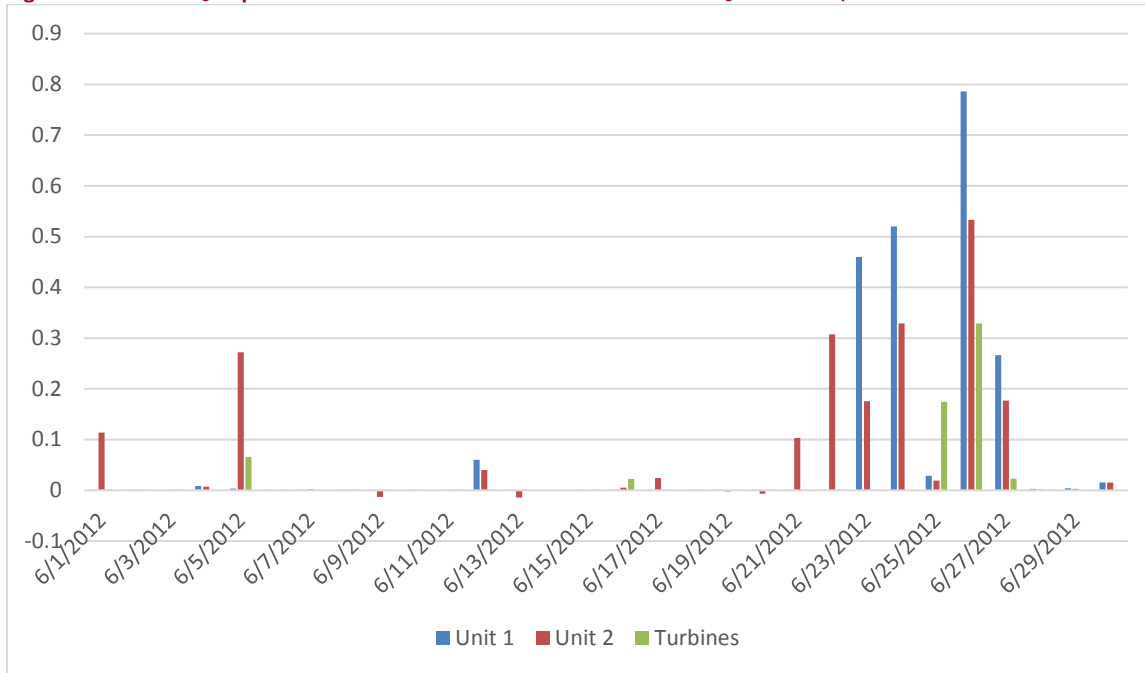

**Table 4-5. MDA8 O<sub>3</sub> Impact - NO<sub>x</sub> Emissions Change Impact Ratios for Non-Road TERP Grants, 2012**

Baseline MDA8 O <sub>3</sub> Rank	CAMS 3 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )	CAMS 38 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )
1	0.0920	0.0784
2	0.0335	0.1310
3	0.0278	0.1049

10	0.0339	0.0582
<b>Avg. Top 4 Days</b>	0.0601	0.1449
<b>Avg. Top 10 Days</b>	0.0562	0.0867

#### 4.4 Reducing NO<sub>x</sub> Emissions at Decker Creek Power Plant

In 2017 AACOG conducted photochemical modeling of the impact of zeroing out NO<sub>x</sub> emissions at each of the two boiler units and all of the turbines at the Decker Creek Power Plant in June 2012 in order to develop data that could be used for estimated the impact reducing NO<sub>x</sub> emissions at this facility, including the possible closure of the two boiler units in 2020 and 2021 as described in Austin Energy's most recent update to their generation plan. The figure below shows the modeled impact of each scenario on MDA8 O<sub>3</sub> values in June 2012.

**Figure 4-3. MDA8 O<sub>3</sub> Impacts of Decker Boilers and Turbines on MDA8 O<sub>3</sub> at CAMS 3, June 2012**

CAPCOG compared the O<sub>3</sub> impact to each unit’s NO<sub>x</sub> emissions on the same day, calculating O<sub>3</sub> impact/NO<sub>x</sub> emissions ratios for each day, and then also for the days with the top 4 and top 10 MDA8 O<sub>3</sub> values at CAMS 3.

**Table 4-6. MDA8 O<sub>3</sub> Impact - NO<sub>x</sub> Emissions Change Impact Ratios from Decker Unit 1 NO<sub>x</sub>, June 2012**

Baseline MDA8 O <sub>3</sub> Rank	CAMS 3 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )	CAMS 38 Impact Ratio (ppb O <sub>3</sub> /tpd NO <sub>x</sub> )

<b>Avg. for Top 4 Days at CAMS 38</b>	0.5435	0.0000	0.0717	0.6222

#### 4.5 Comparison of Impact Ratios

The following graph summarizes the impact ratios for each of the sensitivity or control strategy analyses detailed above.

Figure 4-4. Comparison of the MDA8 O<sub>3</sub> Impact of NO<sub>x</sub> Reductions at CAMS 3 and 38 (ppb O<sub>3</sub>/tpd NO<sub>x</sub>)

## 5 Implications of Other Recent Regional Developments on Ozone

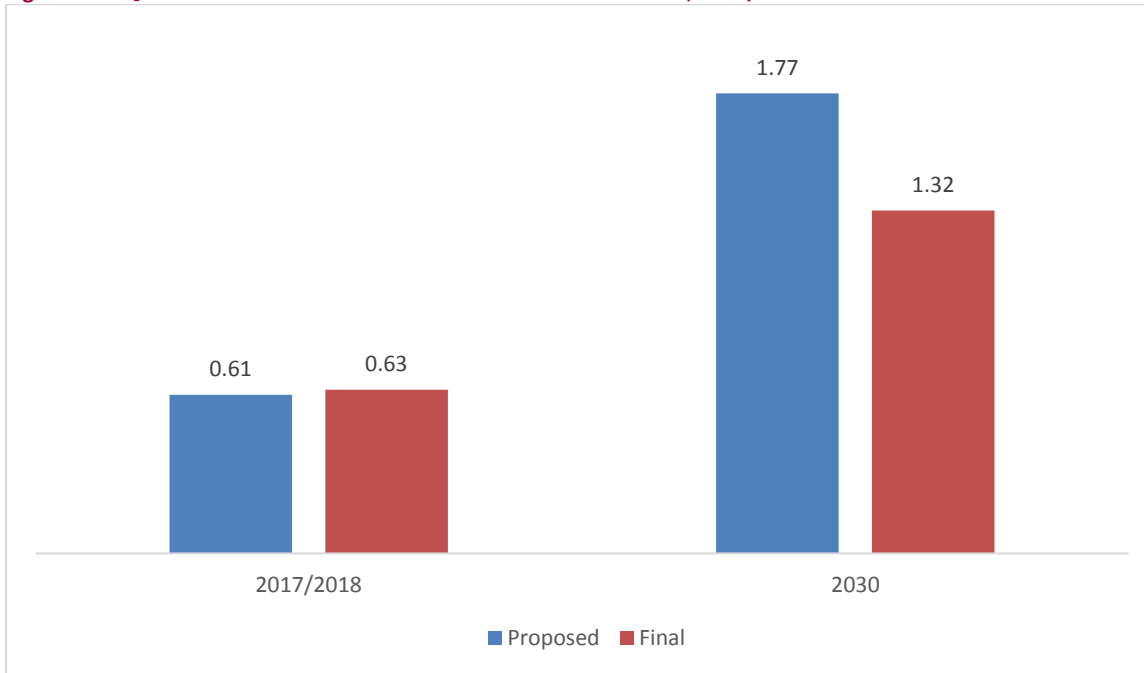

### 5.1 Gasoline Sulfur Reductions

One of the key factors in reductions in NO<sub>x</sub> emissions modeled for the Austin-Round Rock MSA starting in 2017 is the reduction in gasoline sulfur content as a result of EPA’s Tier 3 standards for gasoline and light-duty vehicles. This regulation reduced the maximum allowable gasoline fuel sulfur content at the refinery gate from 30 ppm to 10 ppm, which enables a higher degree of NO<sub>x</sub> reductions from pollution control equipment on light-duty vehicles, while allowing for downstream sulfur content of up to 95 ppm.

As documented in the modeling for the final rule<sup>8</sup> and proposed rule (each of which used different base cases), the Tier 3 standards are modeled to have had an impact of 0.61 – 0.63 ppb for 2017/2018, and raising to 1.32 – 1.77 ppb for 2030.

<sup>8</sup> <http://nepis.epa.gov/Exe/ZyPDF.cgi/P100HX23.PDF?Dockkey=P100HX23.PDF>

**Figure 5-1. O<sub>3</sub> Reduction Benefit of Tier 3 Fuel and Vehicle Standards, 2017/2018 and 2030**

EPA’s emissions modeling technical support document indicated the on-road MOVES emissions inputs that varied by scenario.<sup>9</sup> The table below summarizes these inputs.

**Table 5-1. Emissions Inputs for Final Tier 3 Vehicle Standards**

Input	Reference Scenarios	Control Scenarios
Fuel Sulfur Level (ppm)	30 ppm	10 ppm
% of Tier 2 and Older Vehicles, 2018	96%	86%
% of Tier 2 and Older Vehicles, 2030	76%	21%

These rules were finalized and published in the Federal Register on April 28, 2014. TCEQ’s “Trends” Emissions Inventories for 1999-2050, developed in August 2015, used the MOVES2014 model and it assumed a 10 ppm gasoline sulfur level for 2017 and thereafter, consistent with the maximum allowable concentration at the refinery gate.<sup>10</sup>

CAPCOG’s review of TCEQ’s 2017 fuel sampling data for the region showed that the average gasoline sulfur levels for the region are actually 30 ppm, rather than the 10 ppm modeled by EPA, making it again the highest in the state, while the state-wide average was also almost double the 10 ppm level modeled by EPA and Texas Transportation Institute (TTI).<sup>11</sup> The statewide average was also 19.85 ppm,

<sup>9</sup> <http://nepis.epa.gov/Exe/ZyPDF.cgi/P100HX5N.PDF?Dockkey=P100HX5N.PDF>

<sup>10</sup> [ftp://amdaftp.tceq.texas.gov/pub/EI/onroad/mvs14\\_trends/reports/mvs14\\_trends\\_final\\_report\\_aug\\_2015.pdf](ftp://amdaftp.tceq.texas.gov/pub/EI/onroad/mvs14_trends/reports/mvs14_trends_final_report_aug_2015.pdf)

<sup>11</sup> <https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/ei/582177149010-20170831-ergi-2017SummerFuelFieldStudy.pdf>

considerably higher than the 10 ppm level modeled by EPA and TTI. The Austin area’s sulfur levels were also the highest in the state in the 2011<sup>12</sup> and 2014<sup>13</sup> fuel sampling studies.

**Figure 5-2. TxDOT Region Gasoline Sulfur Properties in 2011, 2014, and 2017 Fuel Sampling Studies**

The Austin district’s average gasoline sulfur levels have been the highest in the state and 50-61% higher than the state average in all of these studies.

The main implication of the 2017 fuel sampling data is that the state and the Austin area in particular did not receive the full emission reduction benefit of the Tier 3 standards adopted by EPA that had been modeled for the first year of the implementation of these standards. While the downstream levels are in compliance with the downstream caps, the higher-than-expected sulfur content in the area’s and state’s gasoline means that the expected NO<sub>x</sub> reductions that will occur between 2017 and 2023 may not be as large as has previously believed.

Notably – all fuel sampled within the Austin District was as low as 10 ppm. The following table shows a summary of the samples collected within the region.

**Table 5-2. 2017 Gasoline Sulfur Content Sampled in the Austin District (ppm)**

Station	City	County	Regular	Medium	Premium
1625 E. Parmer Ln.	Austin	Travis	36	26	17
7200 N IH 35	Austin	Travis	35	29	19

<sup>12</sup> [https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/mob/5821199776FY1103-20110831-ergi-summer\\_2011\\_fuels.pdf](https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/mob/5821199776FY1103-20110831-ergi-summer_2011_fuels.pdf)

<sup>13</sup> [https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/mob/5821199776FY1420-20140815-ergi-summer\\_2014\\_fuels.pdf](https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/mob/5821199776FY1420-20140815-ergi-summer_2014_fuels.pdf)

Station	City	County	Regular	Medium	Premium
2501 S. Water St.	Burnet	Burnet	26	22	15
<b>Avg.</b>	<b>Avg.</b>	<b>n/a</b>	<b>31.4</b>	<b>24.8</b>	<b>16.8</b>

Using just the samples collected in the City of Austin and the same 2015 fuel market share data used by Eastern Research Group (ERG) for the 2017 study, there’s an even higher gasoline sulfur average of 33.7 ppm. Using the 2017 gasoline fuel market share now available from the Energy Information Administration (86.10% regular, 6.42% medium, 7.48% premium),<sup>14</sup> the City of Austin average would be 33.6 ppm (compared to 29.89 ppm for the weighted average for all five stations in the district). Without additional modeling, it’s not clear exactly what the impact of this elevated sulfur level is having on emissions or regional O<sub>3</sub> levels. A TTI sensitivity analysis for the MOVES2010 model did include an analysis of the difference in NO<sub>x</sub> emissions for Tier 2 and earlier gasoline vehicle NO<sub>x</sub> emissions for 2008 – 2030, including at the 30 ppm and 10 ppm levels.<sup>15</sup> CAPCOG conducted an analysis of the potential impact of the elevated gasoline sulfur levels sampled in the 2014 study as part of a report to TCEQ in 2015. A modified version of the table presented in that report is reproduced below for 2017-2023.

**Table 5-3. NO<sub>x</sub> Emissions for Tier 2 and Older Gasoline Vehicles from TTI MOVES 2010 Sensitivity Analysis, 2016-2023**

<b>Change 2017-2023</b>	-62,636	-62,479	157	-0.25%
<b>% Change 2017-2023</b>	-34.00%	-34.25%	0.25%	0.73%

Based on the dependency of the Tier 3 vehicle standards on 10 ppm gasoline sulfur level, we can assume that the 34.00% reduction in NO<sub>x</sub> emissions between 2016 and 2023 for the 30 ppm scenario above represents the most that can be achieved from gasoline vehicles due to fleet turnover during this time frame if the 30 ppm average in the Austin area persisted through 2023. This effectively would mean that whatever extra emission reductions that could be achieved from pollution control equipment on Tier 3 vehicles not achievable from Tier 2 vehicles would be negated, leaving their emission rates as comparable to new Tier 2 vehicles. This reduction in emissions can then be compared to the difference in emissions from the most recently modeled “Trends” emissions reductions produced by TTI using the MOVES2014 model and incorporating the Tier 3 standards. Using Travis County as a reference point, the TTI MOVES2014 “Trends” inventory estimates a 58% in NO<sub>x</sub> emissions from gasoline-powered vehicles

between 2016 and 2023. The following figure compares the projected reductions from a 2016 base year based on the 30 ppm scenario described above and a 10 ppm sulfur level for Travis County.

**Figure 5-3. Comparison of NO<sub>x</sub> Emissions for Gasoline Vehicles Relative to 2016 based on 10 ppm and 30 ppm Gasoline Sulfur Scenarios**

This analysis suggests that the on-road NO<sub>x</sub> emissions in the Austin area in 2017 may have been as much as 31% higher than TTI’s MOVES 2014 trends inventory suggests, and that the relative difference grows such that by 2023, actual on-road NO<sub>x</sub> emissions in the area may be more than 63% higher than what TTI’s Trends Inventory suggests. This also suggests that the projected O<sub>3</sub> levels modeled by AACOG using some of these projections by TTI may overshoot the magnitude of O<sub>3</sub> reduction that that would be expected within the Austin area between 2017 and 2023, leaving a higher risk of potential violation of the NAAQS within that timeframe without any additional emission reductions.

The uncertainty regarding the magnitude of NO<sub>x</sub> reductions expected from fleet turnover between 2017 and 2023 also reinforces the need for the I/M program in order to minimize emissions from gasoline-powered vehicles. To the extent that elevated sulfur content remains high through 2023, the absolute emission reductions from the I/M program will be higher than what would be expected based on TTI’s “Trends” inventory and application of the NO<sub>x</sub> reduction ratio for 2018 based on ERG’s 2015 study.

## 5.2 Shut-Down of Three Coal-Fired Power Plants in 2018

In late 2017, Luminant announced the closure of three large coal-fired power plants (Big Brown, Monticello, and Sandow), including one (Sandow) that is located quite close to the Austin-Round MSA. These three base-load plants collectively accounted for 27,578,352 MW-hours of electricity generated in 2017 and 16,486.31 tons of NO<sub>x</sub> emissions in 2017. The closure of these plants will shift the electricity load to other plants across the state, with the average increase across all plants of 9.1% for the year and

an 8.7% increase from May - September. This makes an analysis of the impact of these closures more complicated than simply estimating the O<sub>3</sub> reduction attributable to the reduction in emissions from these three plants. The average NO<sub>x</sub> rate of these three plants – 1.19 lbs NO<sub>x</sub>/MW-hr, is substantially higher than the average for the remaining fossil-fueled plants in the state – 0.62 lbs NO<sub>x</sub>/MW-hr, which suggests that there would be a net reduction in NO<sub>x</sub> emissions overall. However, this type of an analysis ignores the extent to which the shift in load may be uneven across the state. If baseload plants don't have much of an ability to increase output, more of the load will shift to peaker plants, which tend to have even higher NO<sub>x</sub> emissions rates than some of these older coal plants (all of the Decker and Sim Gideon units had higher NO<sub>x</sub> emissions rates in 2017 than all of the units that are being shut down).

Assuming that the load was spread evenly across all fossil fuel plants in Texas, the following table summarizes the emissions impact and net MDA8 O<sub>3</sub> impact of the changes at Sandow and the power plants within the area based on UT's prior point source modeling and – for Decker- the most recent AACOG modeling.

## 6 Conclusions

This report included a number of secondary analyses of existing photochemical modeling data in order to improve the understanding of ground-level O<sub>3</sub> formation within the region. Broadly, what these analyses indicated were:

1. While the Austin-Round Rock MSA is currently attaining the 2015 O<sub>3</sub> NAAQS through the end of the 2017 O<sub>3</sub> season and is highly likely to remain in attainment of the NAAQS through the end of the 2018 O<sub>3</sub> season, there are still significant risks of the region violating the NAAQS at some point within the 2019 – 2023 time frame, with the probability dropping from 36% for the 2017-2019 O<sub>3</sub> DV to 18% for the 2021-2023 DV.

2. There is a 26% chance that the region's 2019-2021 DV, which will likely be used for the next round of O<sub>3</sub> NAAQS designations, would exceed the current 70 ppb NAAQS, and a 73% chance that it would exceed a more stringent 65 ppb NAAQS.
3. Approximately 99% of the impact of anthropogenic emissions from within the Austin-Round Rock MSA on MDA8 O<sub>3</sub> levels in the region is attributable to emissions of nitrogen oxides (NO<sub>x</sub>), and only approximately 1% is attributable to emissions of volatile organic compounds (VOC)
4. A tpd of NO<sub>x</sub> emissions from Travis County has approximately 2-4 times the impact of NO<sub>x</sub> emissions from the other four counties in the MSA
5. A ton of NO<sub>x</sub> emissions that occurs between 9 am and 11 am has 2.5 – 4.6 times the impact of a ton of NO<sub>x</sub> emissions between 7 am – 9 am or 11 am – 2 pm.
6. The I/M program and NO<sub>x</sub> reductions from Decker units 1 and 2 have a higher MDA8 O<sub>3</sub> impact per ton of NO<sub>x</sub> reduced than an across-the-board reduction in NO<sub>x</sub> emissions from within the Austin-Round Rock MSA, whereas NO<sub>x</sub> emissions from Decker's turbines has a much lower impact per ton of NO<sub>x</sub> reduced.
7. NO<sub>x</sub> emissions reductions from the TERP program have a somewhat higher-than-average impact on MDA8 O<sub>3</sub> formation at CAMS 3 and a somewhat lower-than-average impact on MDA8 O<sub>3</sub> formation at CAMS 3.
8. Closure of Decker Unit 1 no later than the beginning of the 2021 O<sub>3</sub> season, as envisioned in Austin Energy's most recent generation plan will be important to the region's ability to minimize the chances of violating the NAAQS.
9. The higher than expected gasoline sulfur levels raise questions about the pace of projected O<sub>3</sub> reductions in the Austin-Round Rock MSA and highlight the need for maintaining the I/M program in order to control on-road NO<sub>x</sub> emissions.
10. The recent closure of several coal-fired power plants across the state is expected to have a positive impact on O<sub>3</sub> levels within the Austin-Round Rock MSA, even with the shift of that load towards plants within the MSA.
